Application Description and Main Features

- The School Store Inventory Management System is a Java application for managing stock items in a school store. It uses Java Swing for the graphical user interface and stores item objects in an array while the program is running.
- The system has the following main features;
- • Add items with a name, category, quantity and unit price.
- • View stock items in a table and search by item name. • Restock items and issue available stock.
- • Prevent invalid quantities and prevent issuing more stock than is available.
- • Calculate the total value of all stock.

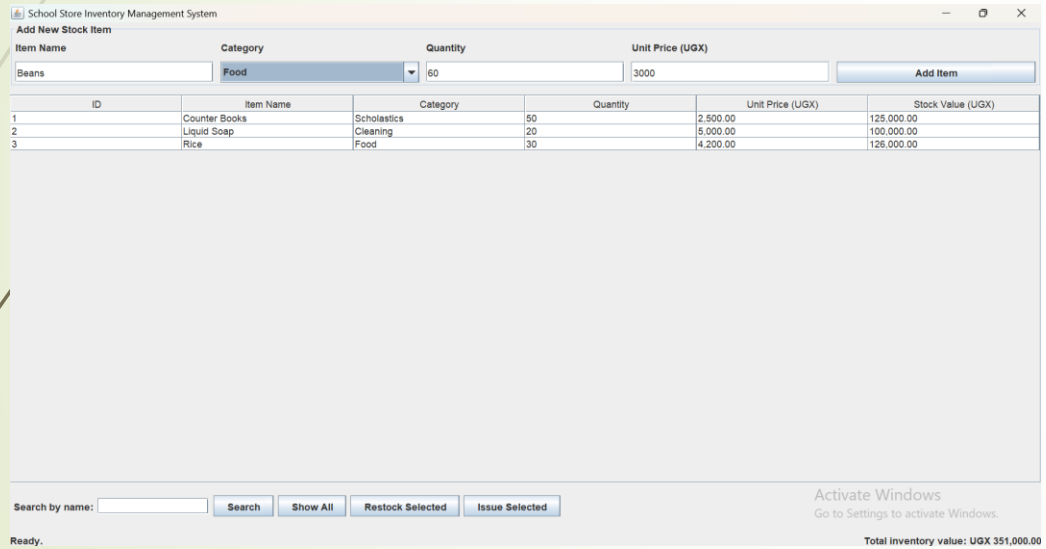

How the Classes Interact and their purpose

- InventoryManagementGUI creates a StoreInventory object. When the user adds an item, StoreInventory creates an Item object and stores it in its Item array. The GUI calls methods on StoreInventory to search and display items. For restocking and issuing, the GUI finds the selected Item and calls its restock() or issueStock() method.

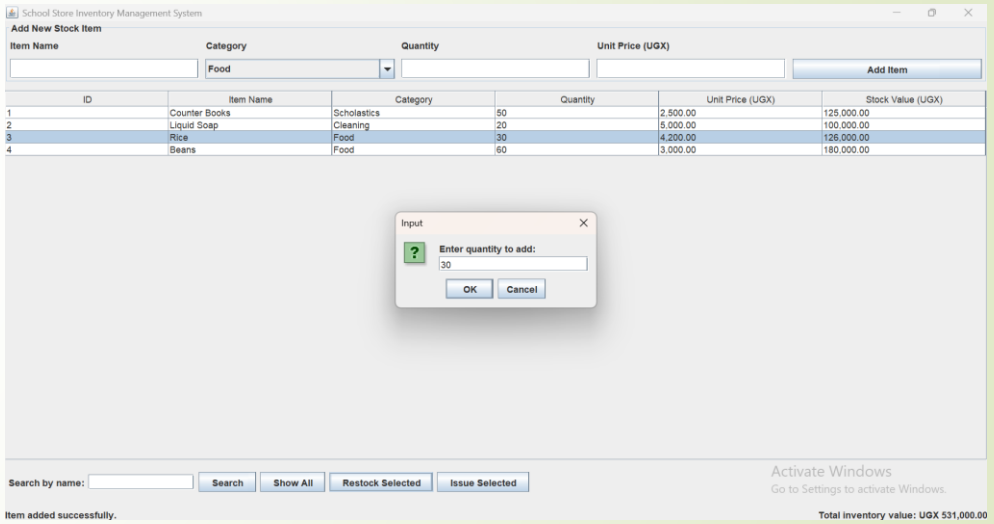

class	purpose
Item	Represents one item. Holds private attributes, a constructor, getters/setters, restock and issue methods
StoreInventory	Manages an array of Item objects. Adds and searches items and calculates the total inventory value.
InventoryManagemwntGUI	Builds the Swing window, reads user input, handles button actions, and displays inventory information

Some of the GUI screens

- Describes adding item

Describes add stock to item

GUI continuation

- Describes issuing item from stock
